**Abstract** Abstract

## 1 Introduction

Silicon photonics is a field of study of manipulating light using silicon-based materials as the optical medium [1]. Most popular choice of material for the optical medium include silicon (Si) and silicon nitride ( $\text{Si}_3\text{N}_4$ ), and the advantage of using silicon-based materials is the compatibility with the already-existing silicon electronics industry. Silicon photonic devices have various applications including optical communications, signal processing and sensing.

This course provides a brief introduction to silicon photonics and some of the basic concepts used in this field. A model circuit was simulated, fabricated and analysed for the purpose of understanding the principles of silicon photonics.

More specifically, in this report, I investigate a Mach-Zehnder interferometer circuit with different path differences. I will be using strip waveguides with 220nm height and 500nm width for quasi-TE modes, and the path difference between 5 and 350  $\mu\text{m}$ .

## 2 Theory

In this study, I will use a Mach-Zehnder interferometer (MZI), which consists of a splitter, waveguides connected to each output, which are later combined. If the lengths of the two waveguides are the same, it's classified as a balanced MZI, otherwise an unbalanced MZI. Here, MZIs with different path length differences will be

investigated. It can be shown that the output electric field of an unbalanced MZI is:

$$E_{output} = \frac{E_{input}}{\sqrt{2}} \left( e^{-i\beta L_1} + e^{-i\beta L_2} \right),$$

where  $E_{output}$  and  $E_{input}$  are the output and input electric fields,  $\beta$  is the propagation constant given by  $2\pi n/\lambda$ ,  $L_1$  and  $L_2$  are the lengths of each waveguide arm. Hence, the intensity of light at the output is:

$$I_{output} = \frac{I_i}{4} \left( e^{-i\beta L_1} + e^{-i\beta L_2} \right) = \frac{I_i}{2} (1 + \cos(\beta \Delta L))$$

where  $\Delta L$  is the path length difference,  $L_1 - L_2$ .

## 3 Modelling and Simulation

The waveguide parameters used for this study is 220nm height, 500nm width for quasi-TE polarisation. The fundamental TE mode profile is shown in Figure\ref{789066} below, obtained from Lumerical MODE.

**Fig. 1** TE0 mode profile, calculated from Lumerical MODE

The effective index of the waveguide can be approximated by second order Taylor series expansion around the centre wavelength of 1.55 micron, and we call it the compact model for the waveguide. From sweeping the frequency for the waveguide simulations and fitting the waveguide, the following expression was obtained:

$$n_{eff} = 2.45 - 1.1(\lambda - 1.55) - 0.43(\lambda - 1.55)^2$$

where  $n_{eff}$  is the effective refractive index, and  $\lambda$  is the wavelength in microns. The effective index and group index at different wavelengths are shown in Figure 2 and 3.

Fig. 2 Effective refractive index at different wavelengths

Fig. 3 Group index at different wavelengths

The free spectral range (FSR) is a parameter that can be used to characterise a MZI, which is given by:

$$FSR = \frac{\lambda^2}{n_g \Delta L}$$

where  $n_g$  is the group index. This is also the difference in the neighbouring minima or maxima. By having multiple circuits with different path length differences and comparing with the calculated FSR, we can estimate the group index of the waveguide. This estimated group index can then be compared with the simulated group index from Lumerical MODE. As an example, FSR is plotted against different path differences, with 1.55 micron wavelength and 4.24 group index in Figure 4, and some representative values given in Table 1.

Fig. 4 FSR at different path differences

| FSR (nm) | Path difference (micron) |
|----------|--------------------------|
| 5.67     | 100                      |
| 2.83     | 200                      |
| 1.89     | 300                      |
| 1.42     | 400                      |
| 1.13     | 500                      |

Table 1 FSR at selected path differences

The photonic circuit can be simulated with Lumerical INTERCONNECT. A sample schematic is shown in Figure 5, and the resulting spectrum from the simulation in Figure 6.

## 4 Fabrication

## 5 Experimental Data

## 6 Analysis

## 7 Conclusion

## 8 Acknowledgements

I/We acknowledge the edX UBCx Phot1x Silicon Photonics Design, Fabrication and Data Analysis course, which is supported by the Natural Sciences and Engineering Research Council of Canada (NSERC) Silicon Electronic-Photonic Integrated Circuits (SiEPIC) Program. The devices were fabricated by Richard Bojko at the University of Washington Washington Nanofabrication Facility, part of the National Science Foundation's National Nanotechnology Infrastructure Network (NNIN), and Cameron Horvath at Applied NanoTools, Inc. Enxiao Luan performed the measurements at The University of British Columbia. We acknowledge Lumerical Solutions, Inc., Mathworks, Mentor Graphics, Python, and KLayout for the design software.
